Minimally invasive endodontics (MIE) is a concept of maximum preserve the healthy coronal, cervical and radicular tooth structure during the endodontic treatment. For success, the dentist must aware between conservation and elimination of tooth structure during endodontic procedure to fulfill the endodontic goals.

Minimally Invasive Endodontics a Promising Future Concept ...

Abstract. Minimally invasive endodontics (MIE) aims to preserve the maximum of tooth structure during root canal therapy. In the last 15 years there has been rapid progress and development in endodontics, making treatment procedures safer, more accurate, and more efficient. Meanwhile, reproducible results can be achieved even in difficult root canal morphologies with severe or double curvatures.

Minimally invasive access to the root canal system is described, and detailed attention is devoted to the application of novel strategies in root canal instrumentation and disinfection, root canal filling, coronal restoration, retreatment, and endodontic surgery. Minimally invasive alternatives to complete endodontic treatment, such as vital pulp therapies, and to dental extraction and implant placement, including surgical extrusion, intentional replantation, and tooth autotransplantation ...

Minimally Invasive Approaches in Endodontic Practice

With advancement in research new insights in pulp biology have developed overtime, a clinical research on vital pulp therapy now provides options for enveloping new biologically driven treatment protocols³. Minimally invasive endodontics treatment modalities include two major rewards: firstly, preservation and maintaining physiological and defensive functions; secondly, lesser removal of hard tissue

The question regarding the philosophy of minimally invasive technique and technology must be in the context of the rationale for endodontics: Endodontics has a 100% capacity for repair if the root canal system can be cleaned and sealed either nonsurgically or surgically. 7 Do current minimally invasive thinking, techniques, and technologies produce more or less predictably successful endodontic outcomes?

of minimally invasive endodontics (MIE) has ignited a discus-sion between proponents of well-shaped canals and those who advocate more minimally prepared canals. Although well intended, this shaping shift, alone, will never fulfill the biologi-cal objectives for success. To forward the concept of MIE will

ENDODONTIC TRIAD FOR SUCCESS: T MINIMALLY INVASIVE TECHNOLOGY

The evolving landscape of modern endodontics is focused on pushing the boundaries of success rates further than the profession's long-standing data on tooth survival. Although successful treatment will hopefully last a lifetime, actual success rates are reported to range between 82%¹ and 97%.² With the goal of improved tooth survival, the future of endodontics is heading toward more minimally invasive, restorative-driven root canal therapy.

Activated Irrigation in Endodontics - Decisions in Dentistry

The concept of minimally invasive endodontics calls for the treatment and prevention of pulpal pathoses and apical periodontitis, while causing the least amount of change to the dental hard tissues. This preserves the strength and function of the endodontically treated tooth with the intent that it will last the patient's lifetime. These skills include working with new instruments and irrigants for cleaning the system; utilising advanced imaging modalities and computer software for ...
