Numerical Solution Wave Equation

The solution of the wave equation is a time-dependent pressure field $u(t,x)$, with $x \in \Omega$ and $t > 0$. Here Ω denotes the set of points inside the environment to be simulated; in realistic situations Ω is three-dimensional, but we shall often resort to lower-dimensional examples for easier presentation.

Theorem: Assume that the two rows of values $u_{i,1} = u(x_i,0)$ and $u_{i,2} = u(x_i,k)$, for $i = 1,2,\dots,n$, are the exact solutions to the wave equation. If the step size $k=h/c$ is chosen along the t -axis, then $r = 1$ and we have

Abstract: We formally prove correct a C program that implements a numerical scheme for the resolution of the one-dimensional acoustic wave equation. Such an implementation introduces errors at several levels: the numerical scheme introduces method errors, and floating-point computations lead to round-off errors.

Numerical solution of the problem is shown on Fig. (4.5). Example 3. Vibrating String Use the explicit method (4.9) to solve the wave equation for a vibrating string: $u_{tt} = c^2 u_{xx}$ for $x \in [0,L]$ and $t \in [0,T]$, (4.16) where $c = 1$ with the boundary conditions $u(0,t) = u(L,t) = 0$. Assume that the initial position and velocity are

The numerical solution of blow-up problems for nonlinear wave equations on unbounded spatial domains is considered. Applying the unified approach, which is based on the operator splitting method, we construct the efficient nonlinear local absorbing boundary conditions for the nonlinear wave equation, and reduce the nonlinear

There are one way wave equations, and the general solution to the two way equation could be done by forming linear combinations of such solutions. The solutions of the one wave equations will be discussed in the next section, using characteristic lines $ct - x = \text{constant}$, $ct + x = \text{constant}$.

Numerical solution of the KdV equation $u_t + u \cdot u_x + 6 \cdot 2 \cdot u \cdot x \cdot x = 0$ ($\delta = 0.022$) with an initial condition $u(x, 0) = \cos(\pi \cdot x)$. Its calculation was done by the Zabusky-Kruskal scheme. The initial cosine wave evolves into a train of solitary-type waves.
